#### **ABSTRACT**

Rule-based diagnostics of power generating equipment is an important task in industry. Diagnostics typically requires rules that process sensor signals, determine patterns in the signals, and produce notification messages when undesirable patterns are found. In Siemens such rules are data-dependent in the sense that they rely on specific characteristic of individual equipment and thus a complex diagnostic task may require a rule set with up to hundreds of such rules. Authoring and maintaining such rule sets is a challenging task that requires automation. In this demo we present how semantic technologies can enhance diagnostics. In particular, we present our semantic rule language sigRL that is inspired by the real diagnostic languages in Siemens. sigRL allows to write compact yet powerful diagnostic programs by relying on a high level data independent vocabulary, diagnostic ontologies, and queries over these ontologies. We present our diagnostic system SemDig. The attendees will be able to write diagnostic programs in SemDig using sigRL over 50 Siemens turbines. We also present how such programs can be automatically verified for redundancy and inconsistency. Moreover, the attendees will see the provenance service that SemDig provides to trace the origin of diagnostic results.

## 1 INTRODUCTION

Diagnostic systems play an important role in industry since they help to maximise equipment's up-time and minimise its maintenance and operating costs [10]. In the energy sector companies like Siemens often rely on *rule-based* diagnostics to analyse power generating equipment by, e.g., testing newly deployed electricity

generating gas turbines [5], or checking vibration instrumentation [7], performance degradation [8], and faults in operating turbines. For this purpose diagnostic engineers create and use complex diagnostic rule-sets to detect equipment abnormalities.

An important class of rules that are commonly used in Siemens are *signal processing rules* (SPRs) that allow to (1) filter, aggregate, combine, and compare *signals*<sup>1</sup> coming from sensors installed in equipment and (2) fire notification messages when a certain pattern in signals is detected. *Authoring* and *maintaining* SPR based rulesets is a challenging problem. We now discuss the challenges in mode details and then present our solution to address them.

Challenges with Authoring SPRs. The main challenge for authoring is that SPRs in most modern industrial diagnostic systems including the ones used in Siemens are highly data dependent in the sense that specific characteristic of individual sensors and pieces of equipment are explicitly encoded in SPRs. As the result for a typical turbine diagnostic task engineers have to write from dozens to hundreds of SPRs that involve hundreds of sensor ids, component codes, sensor and threshold values as well as equipment configuration and design data. For example, a typical Siemens gas turbine has about 2,000 sensors and a typical diagnostic task to verify that the purging<sup>2</sup> is over in the main flame component of a given turbine requires around 300 SPRs, most of which are similar in structure but different equipment specific data values. Thus, there is a need in industry, and in particular in Siemens for a higher level diagnostic rule language that allows to express what the diagnostic task should do rather than how it should do it for specific equipment. Such language should be high level, data independent, while powerful enough to express in a concise way most of typical diagnostic tasks in Siemens.

Challenges with Management of SPRs. Development of a diagnostic rule-set is typically a collaborative and open-ended process by a group of diagnostic engineers. Thus, the engineers may introduce rules that either repeat what other rules already express or contradict them, i.e., by stating that purging is 'over' while the other rules say that is it 'in progress'. The former problem of redundancy in diagnostic rule-sets affects the performance of diagnostics and the latter of inconsistency among rules makes diagnostic results counter-intuitive and unreliable. Moreover, the larger the rule-set

Conference'17, Washington, DC, USA

 $<sup>^1\</sup>mathrm{Signals}$  are are time stamped sequences of measurement values.

<sup>&</sup>lt;sup>2</sup>Purging is the process of flushing out liquid fuel nozzles or other parts which may contain undesirable residues.

gets, the harder it becomes to trace the *provenance* of the messages it fires which again affects the reliability of diagnostic results. Thus, there is a need for semi-automatic rule management support that includes detection of redundancy and inconsistency in rule sets, as well as computation of provenance for diagnostic results.

Our Solution. We rely on semantic technologies to address the the above mentioned challenges. In particular we rely on ontologies [1] to define a novel SPR language and on reasoning [3] over ontologies to foster execution and maintenance of diagnostic tasks. In short, an ontology is a formal conceptualisation of the domain of interest that consists of a vocabulary, i.e., names of classes, attributes and binary relations, and axioms over the terms from the vocabulary that, e.g., assign attributes of classes, define relationships between classes, compose classes, class hierarchies, etc. Since ontologies are specified using a formal logical language such as the W3C standardised ontology web language OWL 2, one can query ontologies and check their properties using reasoning that typically corresponds to logical entailment and implemented in many efficient state-of-the-art reasoning systems such as HermiT [9]. We refer the reader to [1] for more details on ontologies and reasoning.

In order to address the authoring challenge we propose:

- an SPR language sigRL that treats signals as first class citizens and allows to process signals (filter, aggregate, combine, and compare signals) in a high level, declarative, and data independent fashion;
- semantic diagnostic programs that combine sigRL rules
  with diagnostic background knowledge captured using
  ontologies and allow to express complex diagnostic tasks
  in an abstract fashion by exploiting both ontological vocabulary and queries over ontologies to identify relevant
  information (such as sensor ids and threshold values) about
  the equipment that should undergo the diagnostics.

In order to address the management challenge, we developed efficient algorithms to execute diagnostic programs in bottom-up fashion, verify redundancy and inconsistency in diagnostic programs, and to compute provenance that explains the reasons for diagnostic results. Moreover, we implemented our ideas in a system *SemDig* for diagnostics of power generating equipment that (1) allows to author diagnostic programs; (2) offers a tool-kit for management of diagnostic programs, that includes detection of redundancy and inconsistency, as well as provenance computation.

Note that we designed *sigRL* in such a way that, on the one hand, it captures the main signal processing features required by Siemens turbine diagnostic engineers and, on the other hand allows for efficient execution and management of diagnostic programs.

*Demo Overview.* Demo attendees will be able to learn how to do diagnostics of Siemens turbines with sigRL diagnostic programs. To this end we prepared a deployment of our SemDig system on data from 50 Siemens power generating turbines, a diagnostic ontology, and a catalogue of 15 diagnostic tasks. The attendees will be able to load preconfigured diagnostic programs, deploy and execute them, author their own diagnostic programs, and try out our provenance computation and program verification services. See Section 3 for details on demo scenarios.

Due to space limit we put some formal definitions related to our *sigRL* language in the appendix.

#### 2 OUR DIAGNOSTIC SOLUTION

We first introduce our diagnostic language sigRL and then describe our system SemDig.

# 2.1 sigRL Diagnostic Language

In our setting, a signal is a first-class citizen. A signal s is a pair  $(o_s, f_s)$  where  $o_s$  is sensor id and signal function  $f_s$  defined on  $\mathbb{R}$  to  $\mathbb{R} \cup \{\bot\}$ , where  $\bot$  denotes the absence of a value. We assume that we are given a finite set  $S = \{s_1, \ldots, s_n\}$  of basic signals that are readings obtained from a single sensor (e.g., in a turbine) for different time points. We now define signal expressions that filter and manipulate basic signals and create new more complex signals. Intuitively, in our language we group signals in ontological concepts and signal expression are defined on the level of concepts. Then, a signal processing expression is recursively defined as follows:

$$C \leftarrow \alpha \circ C_1 \qquad | agg C_1 \qquad |$$
  
 $C_1 : filterValue(\odot, \alpha) \qquad | C_1 : filterTime(\odot, \alpha) \qquad |$   
 $C_1 : filterAlign C_2 \qquad | C_1 : trend(direction).$ 

where  $C, C_1, C_2$  are concepts,  $\circ \in \{+, -, \times, /\}$ ,  $\alpha \in \mathbb{R}$ , agg is one of min, max, avg, sum,  $\odot \in \{<, >, \le, \ge\}$ ,  $filterAlign \in \{\text{within, after}[t], \text{before}[t]\}$  where t is a period and direction is either  $\{\text{up, down}\}$ . Intuitively, if  $C = \alpha \circ C_1$  then C contains one signal s' for each signal s in  $C_1$  with function defined with  $f_{s'} = \alpha \circ f_s$ , or if  $C_1$ : filterValue( $\odot$ ,  $\alpha$ ) then C contains one signal one signal s' for each signal s in  $C_1$  with  $f_{s'}(t) = \alpha \odot f_s(t)$  if  $f_s(t) \odot \alpha$  at time point t; otherwise  $f_{s'}(t) = \bot$ . The formal meaning of signal processing expressions is defined in [4].

A *diagnostic program* is a tuple  $\Pi = (S, O, M)$  where S is a set of basic signals, O is an ontology<sup>3</sup>, M is a set of signal expressions. Each diagnostic program comes with a set of *message rules* that are defined on top of Boolean combinations of expressions:

$$r = msg(m) \leftarrow D$$
, where  $D := C \mid not C \mid D_1 \text{ and } D_2$ 

We now illustrate our diagnostic programs on the following purging diagnostic task:

Verify that the purging is over in the main flame component of the turbine T1.

Intuitively this task requires to check in the turbine T1 that: (i) the main flame was on for at least 10s and then stopped, (ii) 15s after this, the purging of rotors in the starting-component of T1 started, (iii) 20s after this, the purging stopped. The fact that the purging of a rotor started or ended can be detected by analysing its speed, i.e., by comparing the average speed of its speed sensors with purging thresholds that are specific for individual rotors. The purging diagnostic program can then consist of an ontology with one axiom:

 $SubClassOf(RotorSensor\ SpeedSensor).$ 

<sup>&</sup>lt;sup>3</sup>In order to guarantee efficiency of diagnostics with *sigRL*, we consider a tractable ontology language OWL 2 QL [3] that is standardised by W3C.

two signal processing expressions and one message rule:

PurgingStart = avg rotorStart : value(>, purgingSpeed),

PurgingStop = avg rotorStart : value(<, nonPurgingSpeed),

msg("Purging over") = FlameSensor : duration(>, 10s) :

after[15s] PurgingStart : after[20s] PurgingStop

## 2.2 SemDig Diagnostic System

The main functionality of our semantic rule-based diagnostics system SemDig is to author and maintain sigRL diagnostic programs, to deploy them in turbines, to execute the programs, and to visualise the results of the execution. We now give details of our system by following its architecture in Figure 1 where the solid arrows indicate data flow and dashed—access to ontologies and mappings. There are three essential layers in the architecture: application, rule execution, and signal and data layers. Our system is mostly implemented in Java. We now discuss the system layer by layer.

Application Layer. On this layer, the system offers two front ends and several back end components. The first front end component allows engineers to author, store, load, and maintain diagnostic programs by formulating sets of SPRs as well as message rules in sigRL and sensor retrieving queries. Such formulation is guided by the domain ontology stored in the system. In Figure 2 (left) one can observe a screenshot of the diagnostic program editor which is embedded in the Siemens analytical tool-kit. Another front end component is the semantic Wiki that allows among other features to visualize signals and messages (triggered by programs), and to track deployment of programs in equipment. In Figure 2 (right) one can see visualisation of signals from two components of one turbine. The back end of the application layer consist of components that rely on HermiT [9] ontology reasoning and support consistency and redundancy verification as well as provenance computation. Diagnostic programs formulated in the application layer are converted into XML-based specifications and sent to the rule execution layer that returns back messages and signals. We rely on REST API to communicate between the application layer and the execution layer of our system and OWL API to deal with ontologies.

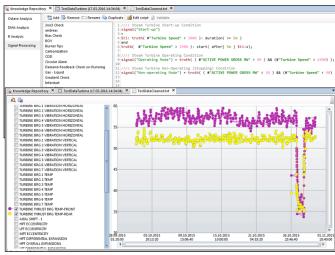

Figure 2: Screenshots: SPR editor (top), Diagnostic visualisation monitor (bottom)

Execution Layer. On this layer we support semantic signals that are either native, that is, represented in terms of the diagnostic ontology as RDF triple, or virtual, that is obtained through the Ontology Based Data Access (OBDA) [6] component of SemDig. This component allows to present signals stored in relational databases as if they were native semantic. This requires to connect the relational signals to an ontology via declarative mappings. For the OBDA layer we rely on the Ontop system [2] that takes care of transforming diagnostic programs written in sigRL into either SPRs written in the Siemens data-driven rule language or SQL. This transformation has two steps: rewriting of programs and queries with the help of ontologies (at this step both programs and queries are enriched with the implicit information from the ontology), and then unfolding them with the help of mappings. Moreover, the execution layer takes care of planning and executing rules and queries received either from the rule management or OBDA component. If the received rules are in the Siemens SPR language then the rule executor instantiates them with concrete sensors extracted with queries and passes them to the Drools Fusion<sup>4</sup> the engine used by Siemens. If the received rules are in SQL then it plans the execution order and executes them together with the other queries.

Signal and Data Layer. On this layer we store all the relevant data: turbine design specifications, historical information about services that were performed over the turbines, previously detected events, and the raw sensor signals. Currently SemDig support PostgresQL, Teradata, as well as Sparksee.

## 3 DEMONSTRATION SCENARIOS

**Demo Setup**. For the demonstration purpose we prepared the following ingredients:

- diagnostic tasks: 15 tasks (see Table 1) were defined during brainstorming sessions with Siemens diagnostic engineers and R&D personnel from Siemens Corporate Technology;
- anonymised Siemens data: from 50 power generating gas turbines gathered for 2 years that contains sensor signals, equipment

 $<sup>^{\</sup>bf 4} http://drools.jboss.org/drools-fusion.html$ 

Task Nr	Complexity	Diagnostic Tasks

14011111	complexity	Diagnostic rusits
T1	Low	Variable guided vanes analyses
T2	Low	Multiple start attempts
Т3	Low	Lube oil system analyses
T4	Medium	Monitoring turbine states
T5	Medium	Interduct thermocouple analyses
T6	Medium	Igniter failure detection
T7	High	Bearing carbonisation
T8	High	Combustion chamber dynamics
T9	High	Gearbox Unit Shutdown
T10	High	Surge detection

- T11 Does the turbine T100 reach purging and ignition speed for 30 sec?
- T12 Is the purging over in the main flame component of the turbine T1.
- T13 Does the turbine T100 reach purging and ignition speed for 30 sec?
- T14 Does the turbine T100 go from ignition to stand still within 1min and then stand still for 30 sec?
- T15 Is the turbine T100 ready to start?

Table 1: Demo diagnostic tasks for Siemens gas turbines.

specifications and configurations and maintenance data; all the data was anonymised for the demo purpose;

- Siemens diagnostic ontology: the ontology was inspired by the Siemens Technical System Ontology (TSO), Semantic Sensor Network Ontology (SSN), and the international standards IEC 81346 and ISO/TS 16952-10; the main module of our ontology in partially depicted in Figure 3 where in grey we present SSN and with white TSO terms. This module has 48 classes and 32 object and data properties. The other three modules are respectively about equipment, sensing devices, and diagnostic rules. They provide detailed information about the machines, their deployment profiles, sensor configurations, component hierarchies, functional profiles and logical bindings to the analytical rule definitions.
- SemDig deployment in Siemens: over both materialised and ontology mediated Siemens data; SemDig is deployed on Teradata for signals and MS SQL for other information; for rule processing SemDig uses Drools Fusion; for the OBDA setting we developed 376 R2RML mappings.

During the demo we can either remotely connect to our deployment at Siemens or to run demo on a laptop. We now explain demo scenarios in details.

Scenario 1: Preconfigured Diagnostics. We plan to present the demo starting from this scenario where the attendees will get acquainted with sigRL and the main functionalities of SemDig. For this purpose we prepared 10 tasks of different complexity, where complexity is de ned using the number of ontological terms and lines of code. These tasks can be found in Table 1, they are indicated as T1-T10. The attendees will start with the tasks of low complexity by loading the corresponding diagnostic programs in the SemDig rule editor, learning the basic signal processing operations of sigRL, and then deploying the programs over the turbines. Then, the attendees will study the diagnostic results on the visualisation monitors. From the visualisation monitor the attendees will be able to request the provenience for specific answers. After the tasks with low complexity the attendees will proceed to the tasks with medium and high complexity. We have intentionally introduced inconsistencies and redundancy in the tasks so that the attendees will be able to detect them using the tooling support of SemDig.

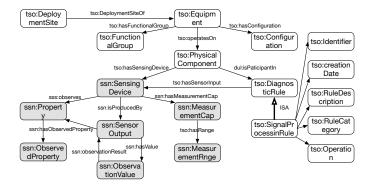

Figure 3: A fragment of the Siemens ontology that we developed to support turbine diagnostic SPRs.

Scenario 2: User Defined Diagnostics. In this scenario we assume that the demo attendees have already learned the basics of sigRL and now they are ready to author diagnostic programs in our editor depicted in Figure 2. For this purpose we prepared five tasks T11–T15 that can be found in Table 1. Note that for simplicity we phrased the tasks T11–T15 in such a way that the wording follows the actual grammer of sigRL. Moreover, most of semantic terms relevant for these tasks are explicitly mentioned in the tasks. Observe that the first four tasks are independant from each other, while the last task, T15, combines the other four. This will show the attendees the compositionality of our language sigRL. For illustration consider the following diagnostic program that corresponds to the task T13:

```
PurgeAndIgnition = PurgingStart : duration(>, 30s) : after[2m] \  \, \text{Ignition} : \text{duration}(>, 30s). msg("Purging \ and \  \, \text{Ignition}") = \text{PurgeAndIgnition}. And now the diagnostic program corresponding to T15: msg("Ready \ to \ Start") = \text{RampChange} : \  \, after[5m] \  \, \text{PurgingOver} : \\ after[11m] \  \, \text{PurgingAndIgnition} :
```

after[15s] IgnitionToStand.

Ignition = avg RotorSensor : value(<, ignitionSpeed).</pre>

While the attendees formulate the five diagnostic tasks as diagnostic programs to check they will be asked to verify them for redundancy and consistency. After they finish formulation and verification, they can run the programs and check provenance.

#### 4 SIGRL DIAGNOSTIC LANGUAGE

In order to capture diagnostic tasks we propose the *sigRL* language that allows to specify diagnostic programs and message rules, and combine them with ontological axioms.

**Diagnostic Programs**. In our language sigRL, a (diagnostic) programs  $\Pi = (\mathcal{D}, \Sigma)$  consisting of two layers: data layer  $\mathcal{D}$  and rule layer  $\Sigma$ . Intuitively, the data layer keeps all the data of interest: signals and details of concrete equipment; the rule layer manipulates the data layer using rules and ontological axioms that are generic for turbines.

The data layer  $\mathcal{D}=(\mathcal{S},\mathcal{A})$  consists of two components: *basic signals*  $\mathcal{S}$  which represent signal data and *class assertions*  $\mathcal{A}$  which define, for instance, types of sensors and asserts types of turbine components, e.g., as follows:

ClassAssertion(RotorSensor 'S21R1T1').

In our setting, a *signal s* is a first-class citizen and defined as a pair  $(o_s, f_s)$  where  $o_s$  is *sensor id* and *signal function*  $f_s$  defined on  $\mathbb{R}$  to  $\mathbb{R} \cup \{\bot\}$ , where  $\bot$  denotes the absence of a value. We assume that we are given a finite set  $S = \{s_1, \ldots, s_n\}$  of *basic* signals that are readings obtained from a single sensor (e.g., in a turbine) for different time points.

The rule layer  $\Sigma = (C, O)$  contains signal processing expressions C and ontological axioms O. Signal expressions filter and manipulate basic signals and create new more complex signals. In our language we group signals in *basic* (ontological) concepts and signal expression are defined on the level of concepts. Formally, a *signal* processing expression is recursively defined as follows:

```
C \leftarrow \alpha \circ C_1 \qquad | agg C_1 \qquad |
C_1 : filterValue(\odot, \alpha) \qquad | C_1 : filterTime(\odot, \alpha) \qquad |
C_1 : filterAlign C_2 \qquad | C_1 : trending(direction).
```

where C,  $C_1$ ,  $C_2$  are concepts,  $\circ \in \{+, -, \times, /\}$ ,  $\alpha \in \mathbb{R}$ ,  $agg \in \{\min, \max, avg, sum\}$ ,  $\odot \in \{<, >, \leq, \geq\}$ ,  $filterAlign \in \{\text{within, after}[t], \text{before}[t]\}$  where t is a period and direction is either  $\{\text{up, down}\}$ .

The formal meaning of signal processing expressions is defined in Table 2. In order to make the mathematics right, we assume that  $c \circ \bot = \bot \circ c = \bot$  and  $c \odot \bot = \bot \odot c = \mathit{false}$  for  $c \in \mathbb{R}$ , and analogously we assume for aggregate functions. If the value of a signal function at a time point is not defined with these rules, then we define it as  $\bot$ .

Let us illustrate signal processing expressions on the running example.

*Example 4.1.* The following expression defines the start of a purging process from the running example:

```
PurgingStart = avg mainSpeedSensor : filterValue(>, purgingSpeed) (1)
```

Intuitively, this rule computes a new signal from a given one s in a bottom-up fashion. First, it computes avg mainSpeedSensor by creating new auxiliary signal s'' with signal function  $f_{s''}(t) = avg_{s \in C_1}f_s(t)$ , i.e., the signal takes an average at each time point t.

Then, using filter filterValue(>, purgingSpeed) it creates s' from s'' by taking only values greater than purgingSpeed. Formally,  $f_{s'}(t) = f_{s''}(t)$  if  $f_{s''}(t) > purgingSpeed$ ; otherwise  $f_{s'}(t) = \bot$ .

Ontological axioms O describe general characteristics of power generating equipment which includes partonomy of its components, characteristics and locations of its sensors, etc. As an example consider the following ontological axioms that says that RotorSensor is a kind of SpeedSensor:

In order to guarantee efficiency of diagnostics with *sigRL*, we consider a tractable ontology language OWL 2 QL [3] that is standardised by W3C and allows to express subclass (resp. sub-property) relationship between classes and projections of properties (resp. between properties).

Message Rules. On top of diagnostic programs  $\Pi$  *sigRL* allows to define *message rules* that report the current status of a system. Formally, they are defined as Boolean combinations of signal processing expressions:

```
msg(m) \leftarrow D, where D := C \mid not D_1 \mid D_1 \text{ and } D_2.
```

Example 4.2. In order to complete our running example in *sigRL* we now define PurgingStop signal processing expression in (3) and then a message rule in (1):

**Semantics of** *sigRL*. We extend first-order interpretations that are used to define semantics of OWL 2 QL axioms. In sigRL, an interpretation I is a pair  $(I_{FOL}, I_S)$  where  $I_{FOL}$  interprets objects and their relationships (like in OWL 2 QL) and  $\mathcal{I}_S$  interprets signals. For brevity, we immediately define when an interpretation  $\mathcal{I}$  is a model of a program  $\Pi = ((S, \mathcal{A}), (C, O))$ . First, we define how I interprets data layer. For the given set of signals  $S: S^I = \{s_1^I, \dots, s_n^I\}$ such that  $I_{FOL}$  'returns' the signal id,  $s^{I_{FOL}} = o_s$  and  $I_S$  'returns' the signal itself,  $s^{I_S} = s$ . For each object o in  $\mathcal{A}$  we define  $o^{I_S}$  as s if o is the id of s from S; otherwise  $(o, f_{\perp})$  where  $f_{\perp}(t) = \{\perp\}$ , for all  $t \in \mathbb{R}$ . Then we define when  $\mathcal{I}$  "models" the rule layer. In particular,  $O^I$  extends the notion of first-order logics interpretation as follows:  $O^{I_{FOL}}$  is a first-order logics interpretation O consistent with  $\mathcal{A}^{I_{FOL}}$ , i.e.,  $I_{FOL} \models (O, \mathcal{A})$ ; and  $O^{I_S}$  is defined for objects, concepts, roles and attributes following  $\mathcal{S}^I$  and  $\mathcal{A}^I$ . For example, for a concept A we define  $A^{I_S} = \{s^{I_S} \mid o_s^{I_{FOL}} \in A^{I_{FOL}}\}$ . Finally, I models C if it satisfies all signal expressions; and this can be defined recursively in a button-up fashion following the definition dependencies between them. For example, if  $C = \text{agg } C_1$  then  $C^{I_S} = \{(o_{\text{agg}}, C_1, f_{\text{agg}}, C_1)\}$ such that  $f_{\text{agg}, C_1}(t) = \text{agg}\{f_s(t) \mid s \in C_1^{I_S}\}$ . And similarly, one can define satisfiability for the other expressions.

<i>C</i> =	Concept <i>C</i> contains	
$\alpha \circ C_1$	one signal $s'$ for each signal $s$ in $C_1$ with $f_{s'} = \alpha \circ f_s$ .	
$agg C_1$	one signal $s'$ with $f_{s'}(t) = \arg_{s \in C_1} f_s(t)$ , that is, $s'$ is obtained from	
$C_1$ : filterValue $(\odot, \alpha)$	all signals in $C_1$ by applying the aggregate agg at each time point $t$ . one signal $s'$ for each signal $s$ in $C_1$ with $f_{S'}(t) = \alpha \odot f_{S}(t)$	
-1 · · (0,)	if $f_s(t) \odot \alpha$ at time point $t$ ; otherwise $f_{s'}(t) = \bot$ .	
$C_1$ : filterTime( $\odot$ , $t'$ )	one signal s' for each signal s in $C_1$ with $f_{s'}(t) = f_s(t)$	
	if exists an interval $I$ such that: $f_s$ is defined $I$ , $t \in I$ and	
	$size(I) \odot t'$ ; otherwise $f_{s'}(t) = \bot$ .	
$C_1$ : filterAlign $C_2$	a signal $s_1$ from $C_1$ if: there exists a signal $s_2$ from $C_2$ that is aligned	
	with $s_1$ , i.e., for each time interval $I_1$ where $f_{s_1}$ is defined there is	
	an interval $I_2$ where $f_{s_2}$ is defined s.t. $I_1$ aligns with $I_2$ .	
$C_1$ : trending(direction)	a signal $s_1$ from $C_1$ if function $f_{s_1}$ is non-decreasing when direction = up;	
	or if function $f_{s_1}$ is non-increasing when <i>direction</i> = down.	

Table 2: Meaning of signal processing expressions. For the interval I, size(I) is its size. For intervals  $I_1$ ,  $I_2$  the alignment is: " $I_1$  within  $I_2$ " if  $I_1 \subseteq I_2$ ; " $I_1$  after[t]  $I_2$ " if all points of  $I_2$  are after  $I_1$  and the start of  $I_2$  is within the end of  $I_1$  plus period t; " $I_1$  before[t]  $I_2$ " if " $I_2$  start[t]  $I_1$ ".
